Q1 **1**4

1) 20 pts

Mark the following statements as TRUE or FALSE. No need to provide any justification.

[TRUE/FALSE]

Any depth-first search in a directed graph will produce the same number of tree edges in the DFS tree.

TRUE/FALSE

For any connected graph with *n* vertices and *m* edges we can say that m+n = O(m).

[TRUE/FALSE]

In a binomial heap, for a given set of input values, the number of binomial trees in the heap will depend on the order of insertions

[TRUE/FALSE]

The amortized cost of an operation can be as high as the worst-case cost of an operation in a data structure.

[TRUE/FALSE]

A recurrence equation of the type $T(n) = a \cdot T(n/b) + f(n)$ where $a \cdot f(n/b) = 2 \cdot f(n)$ cannot be solved using the Master Theorem.

[TRUE/FALSE]

For a given problem instance, an algorithm with a Θ (n²) worst case performance can run faster than an algorithm with a Θ (n log n) worst case performance.

[TRUE/FALSE]

The shortest path between two nodes in a weighted directed graph can be found using BFS if all edges except for those leaving the starting point have the same weight.

[TRUE/FALSE]

Suppose that G is a directed, acyclic graph and has a topological ordering with v_1 the first node in the ordering and v_n the last node in the ordering. Then there is a path in G from v_1 to v_n . False

[TRUE/FALSE]

Consider an execution of Kruskal's algorithm on graph G with n nodes where all the first n-1 edges that we pick from the sorted list end up in the MST. Then we can conclude that G has no cycles.

[TRUE/FALSE]

Kruskal's algorithm for minimum weight spanning trees is an example of a greedy algorithm.

Q2

16

2) 16 pts Consider a special case of the Minimum Spanning Tree problem where the graph G has edge costs of either 1, 3, or 5. We know that we can find an MST in this graph using Prim's algorithm in θ(m log n) when a binary heap is used as the data structure to hold the nodes (in the set V-S). Given the fact that edge costs can either be 1, 3, or 5, create a special data structure (replacing the heap) that will improve this time complexity. In other words, the resulting algorithm should have a worst-case

performance strictly better than $\theta(m \log n)$ on this graph.

The stureting data structure has the following properties.

A ERRY PROD

DIF contains a bucket for each edge length of 1,3.5.
Hence it contains 3 buckets (\$1,3,5).

2) Each node goes unto a particular buchet depending or its edge distance from S. ie a node with an edge dustance of the is from S will go unto bucket is.

3) Thing this we can extract

3) Since win each bucket,

3) We keep picking the expect node from bucket I first.
then 3, then 5.

4) Hence every extract -min operation takes. O(1) unstead

9 0(1091).

Hence the performance can be unproved to Qm) from, o (miosin) by using the hash who smidting

Q3

2

) 16 pts

Suppose you are organizing a company party. The corporation has a hierarchical ranking structure; that is, the CEO is the root node of the hierarchy tree, and the CEO's immediate subordinates are the children of the root node, and so on in this fashion. To keep the party fun for all involved, you will not invite any employee whose immediate superior is invited. Every employee is equally valued, so we would like to maximize the total number of employees invited. Everyone in the corporation hierarchy (including the CEO) is considered an employee.

A) Provide a greedy algorithm to solve this problem. (8 pts)

1) rangue the entire tree and fixed a list of employees with all

2) Sout that hast boos in decreasing order of number of subordinates

3) There are Iterate through the visit and for each element, unvite the subordinates (if they are not already using the uninvited) and

Add this superior to the Just of winning.

Note: All employees with no subordinates will be unuted

B) Prove that your algorithm produces an optimal solution. (8 pts)

In each sky, we are selecting an se employee with the more noigh employees.

a greedy algorithm based on dynamic programming to maximize the number of employees

raverse the hierarchical ranking structure starting from the CEO (root node). You can use first or breadth-first traversal.

or each employee encountered during traversal, maintain two values:

nclude: The maximum number of employees invited if this employee is invited.

xclude: The maximum number of employees invited if this employee is not invited.

or each employee encountered, calculate include and exclude values as follows:

the current employee is invited (include), then their immediate subordinates cannot be invited, the maximum of exclude values of their children to include.

the current employee is not invited (exclude), then you can choose to either include or le their children, so add the maximum of both include and exclude values of their children to

Continue this process until you have traversed the entire hierarchy.

The final result will be the maximum of the include and exclude values of the CEO (root node). Ill give you the maximum number of employees that can be invited without inviting any yee and their immediate superior simultaneously.

a simplifiedPython-like pseudocode for the algorithm:

axEmployees(root):

ot is None:

Q4

4) 10 pts

Arrange these functions under the O notation using only = or \subset (strict subset of): E.g. for the functions n, n+1, n^2 , the answer should be $O(n+1) = O(n) \subset O(n^2)$. No justifications are required.

n³-613, ln(n+4), sin(n⁴), log₂(n⁸⁸ⁿ), 9999, nⁿ, nlog₃(n³), n^{1.1}

$$n^{3}-613 = O(n^{3})$$
 $\ln(n++) = \tan^{3} \log_{e}(n++) = O(\log_{e}n) = O(\log_{e+1}n)$
 $Sin(n^{4}) = O(1)$
 $\log_{e}(n^{38n}) = 38n\log_{2}n = O(\log_{e}n)$
 $10g_{e}(n^{38n}) = 0(1)$
 $10g_{e}(n^{3}) = 0(n^{3})$
 $10g_{e}(n^{3}) = 0(n^{3})$
 $10g_{e}(n^{3}) = 0(n^{3})$

Answer

 $O\left(S_{in}(n^{4})\right) = O\left(9999\right) \subset O\left(I_{n}(n+4)\right) \subset O\left(n\log_{3}(n^{3})\right) = O\left(\log_{2}\left(n^{88n}\right)\right) \subset O\left(n^{14}\right)$ $\subset O\left(n^{3}-613\right) \subset O\left(n^{n}\right)$

Q5

18 pts

Consider the following directed, weighted graph:

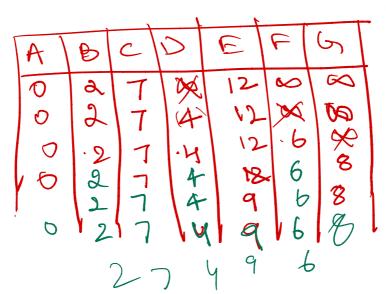

(a) Even though the graph has negative weight edges, step through Dijkstra's algorithm to calculate the supposedly shortest paths from A to every other vertex. Show your steps in the table below. Start with initial distances in the top row of the table and cross out old values (distances) and write in new ones in the row below whenever distances change.

						_
Α	В	С	/D	IST	F	G
0	ÒQ	≥	Da	DO	00	X
	2	7	¥	9/	6/	8
			3		-	2

(b) List the vertices in the order which you marked them known. (3 pts)

A,

- (c) Dijkstra's algorithm found the wrong path to some of the vertices. For just the vertices where the wrong path was computed, indicate both the path that was computed and the correct path. (6 pts)
- (d) What single edge could be removed from the graph such that Dijkstra's algorithm would happen to compute correct answers for all vertices in the remaining graph? (3 pts)

12 Q6

6) 12 pts

Use the Master's Theorem to solve the following recurrence equations (if it applies). Indicate if the Master's Theorem does not apply and give a reason why.

a)
$$T(n) = 3T(n/4) + O(n)$$

Case 3

f(n) is O(n) $3f(n|y) \leq Cf(n) \Rightarrow 3O(n|y) \leq CO(n) \Rightarrow C \Leftrightarrow B$ $5f(n|y) \leq Cf(n) \Rightarrow 3O(n|y) \leq CO(n) \Rightarrow C \Leftrightarrow B \text{ and } C \leq I$ $T(n) \text{ is } \Theta(n)$ $T(n) = 8T(n/4) + O(n^2)$ (3 pts)

 $n^{10948} = n^{1-5} = O(n^{15})$

Case 3

f(n) is $\Omega(n^{1.5})$ and they differ by a polynomial $8000000 \cdot 8(\frac{p^2}{16}) \le C \cdot n^2 = C \cdot 2\frac{1}{2}$ and $C \le 1 \Rightarrow C$ exists · T(n) us 0 (n2)

c) $T(n) = 2^{n}T(n/2) + O(n)$

(3 pts)

Master's theorem does not apply because the number of subproblems (a) cannot be dependent on

n. It a' needs to be a constant value of >1.

d) $T(n) = 9T(n/3) + O(n^2)$

(3 pts)

nlogge = nlogge n2.

f(n) is θ (n 1096)

Case 2.

: T(n) is O(n2 logn).

Q7

() 8 pts

Assume you are creating an array data structure that has a fixed size of *n*. You want to backup this array after every so many insertion operations. Unfortunately, the backup operation is quite expensive, it takes exactly *n* operations to do the backup regardless of how many elements are currently in the data structure (e.g. after 5 insertions, there are 5 elements in the data structure, but the backup still requires exactly *n* operations). Insertions without a backup only take one operation to perform.

a) What is the amortized cost of the insertion operation (after n insertions) if you perform a backup after every n/5 insertions? (4 pts)

If we change unsent 6 and backup 10, with actual costs 1 and n prespectively, Affec n/5 iteration, we have 5xn = n could credit in the bank. Which we can use to pay for the expensive backup operation.

Amortised cost of unsention in O(1)

b) What is the amortized cost of the insertion operation if you perform a backup after every 5 insertions? (4 pts)

If we charge unsent $(\frac{\Pi}{5}+1)$ and backup 0, with actual costs of land n suspectively,

After every 5 interactions, we have $\frac{\Pi}{5}$ $(\frac{\Pi}{5}+1)\times 5 = \frac{\Pi}{5}$ and $\frac{\Pi}{5}$ or $\frac{\Pi}$
